

A note on recurrences

by Jörg W. Müller

Algebraic rearrangements are invariably dull to perform. In addition, they require permanent attention if we want to avoid any error that would render the final result useless. Occasionally, one encounters in such calculations a small problem which may be worth a few moments' thought.

Thus, in the lengthy attempt to evaluate parities for observed counts, when the original Poisson process has been distorted by an extendable dead time, a problem was met which involves summing over alternate moments, defined [1] by

$$m_r^\pm = \sum_{k=0}^{\infty} (-1)^k k^r p_k . \quad (1)$$

If the probabilities p_k follow the Poisson law (with mean value μ), the moment of order $r \geq 1$ is known [1] to be

$$m_r^\pm = e^{-2\mu} \sum_{j=1}^r S(r,j) (-\mu)^j , \quad (2)$$

where S is a Stirling number of the second kind [2].

In the problem encountered, the expression to be evaluated is of the form

$$F = \sum_{j=0}^{r-1} \left\{ \begin{matrix} r-1 \\ j \end{matrix} \right\} m_{j+1}^\pm ,$$

which can be rearranged to become

$$F = e^{-2\mu} \sum_{k=1}^{j+1} (-\mu)^k T(r,k) ,$$

where

$$T(r,k) = \sum_{j=0}^{r-1} \left\{ \begin{matrix} r-1 \\ j \end{matrix} \right\} S(j+1,k) \quad (3)$$

is now the quantity in which we are interested.

Consider, for the sake of curiosity, both the binomial coefficients and the Stirling numbers as triangular matrices of infinite order. In a simplified notation, these are

$$\underline{B} = \begin{pmatrix} 1 & & & & & \\ 1 & 1 & & & & \\ 1 & 2 & 1 & & & \\ \boxed{1} & \boxed{3} & \boxed{3} & \boxed{1} & & \\ 1 & 4 & 6 & 4 & 1 & \\ & & \dots & & & \end{pmatrix} \quad \leftarrow r=4$$

and

$$\underline{S} = \begin{pmatrix} 1 & & & & & \\ 1 & \boxed{1} & & & & \\ 1 & 3 & 1 & & & \\ 1 & 7 & 6 & 1 & & \\ 1 & 15 & 25 & 10 & 1 & \\ & & \dots & & & \end{pmatrix},$$

k=2
↓

where we have put $\binom{0}{0} = 1$ and omitted the Stirling numbers $S(j,0)$ as they are not needed in (3).

If we choose, for example, the values $r = 4$ and $k = 2$, the evaluation of $T(4,2)$, according to (3), involves pairwise multiplication of the terms within rectangles in the above matrices. It is readily seen that this corresponds to a matrix multiplication; hence we can write symbolically

$$\underline{T} = \underline{B} \times \underline{S}, \quad (4)$$

where \underline{T} is now also a matrix.

If we evaluate, for a few arguments, the numerical values of $T(r,k)$, we find the coefficients assembled in Table 1.

Table 1. Some numerical values of $T(r,k)$.

	$k = 1$	2	3	4	5	6
$r = 1$	1					
2	2	1				
3	4	5	1			
4	8	19	9	1		
5	16	65	55	14	1	
6	32	211	285	125	20	1

A closer inspection of Table 1 reveals that its values follow a simple recurrence relation*, namely

$$T(r,k) = (k+1) T(r-1,k) + T(r-1,k-1) . \quad (5)$$

This reminds us of the fact that there exist similar recurrences for the binomial coefficients and for the Stirling numbers. These are known to be

$$B(n,k) = B(n-1,k) + B(n-1,k-1)$$

and

$$S(n,k) = k S(n-1,k) + S(n-1,k-1) ,$$

respectively.

A comparison with (5) and (4) immediately raises the question whether the "transfer" of recurrences is a general feature of matrix multiplication.

To approach this problem, consider a general matrix multiplication $\underline{A} \times \underline{B} = \underline{C}$ and start with the assumed recurrences

$$\begin{aligned} A_{i,j} &= \alpha_1 A_{i-1,j} + \alpha_2 A_{i-1,j-1} , \\ B_{j,k} &= \beta_1 B_{j-1,k} + \beta_2 B_{j-1,k-1} . \end{aligned} \quad (7)$$

* Note that the quantities $T(r,k)$ are identical with coefficients that have been listed before in another context [3], and which were then denoted by $\beta_j(r,2)$. The correspondence is $\beta_j(r,2) = T(r+1, j+1)$. In fact, it now turns out that all the coefficients evaluated in [3] allow simple recurrences, namely (in the original notation)

$$\begin{aligned} \alpha_j(r,t) &= t \alpha_j(r-1,t) + \alpha_{j-1}(r-1,t) \\ \text{and} \\ \beta_j(r,t) &= (j+t) \beta_j(r-1,t) + \beta_{j-1}(r-1,t) , \end{aligned}$$

a property which has not been recognized previously. These relations also provide a convenient means for checking the numerical values.

This gives for the element $C_{i,k}$ of the product matrix

$$\begin{aligned}
C_{i,k} &= \sum_j A_{i,j} B_{j,k} \\
&= \sum_j (\alpha_1 A_{i-1,j} + \alpha_2 A_{i-1,j-1}) (\beta_1 B_{j-1,k} + \beta_2 B_{j-1,k-1}) \\
&= \sum \alpha_1 A_{i-1,j} (\beta_1 B_{j-1,k} + \beta_2 B_{j-1,k-1}) + \sum \alpha_2 A_{i-1,j-1} \beta_1 B_{j-1,k} + \sum \alpha_2 A_{i-1,j-1} \beta_2 B_{j-1,k-1} \\
&= \sum \alpha_1 A_{i-1,j} B_{j,k} + \alpha_2 \beta_1 C_{i-1,k} + \alpha_2 \beta_2 C_{i-1,k-1} \\
&= \alpha_1 C_{i-1,k} + \alpha_2 \beta_1 C_{i-1,k} + \alpha_2 \beta_2 C_{i-1,k-1} \\
&= (\alpha_1 + \alpha_2 \beta_1) C_{i-1,k} + \alpha_2 \beta_2 C_{i-1,k-1} .
\end{aligned} \tag{8}$$

As expected, we return to the situation given in (5) by putting $\alpha_1 = \alpha_2 = 1$, $\beta_1 = k$ and $\beta_2 = 1$.

It is interesting to note in (8) that the coefficients γ , for the product element

$$C_{i,k} = \gamma_1 C_{i-1,k} + \gamma_2 C_{i-1,k-1} , \tag{9}$$

involve not only sums, but also products of the coefficients α and β . The coefficients γ are thus not symmetric in α and β .

It may therefore be worthwhile also to consider triple recurrences, i.e. relations of the form

$$\begin{aligned}
A_{i,j} &= \alpha_1 A_{i-1,j} + \alpha_2 A_{i-1,j-1} + \alpha_3 A_{i-1,j-2} , \\
B_{j,k} &= \beta_1 B_{j-1,k} + \beta_2 B_{j-1,k-1} + \beta_3 B_{j-1,k-2} .
\end{aligned} \tag{10}$$

After a similar, although longer calculation, we can show that the form of the product element $C_{i,k}$ is

$$\begin{aligned}
C_{i,k} &= \left[\alpha_1 + \beta_1 (\alpha_2 + \alpha_3 \beta_1) \right] C_{i-1,k} + \beta_2 (\alpha_2 + 2\alpha_3 \beta_1) C_{i-1,k-1} \\
&\quad + \left[\beta_3 (\alpha_2 + 2\alpha_3 \beta_1) + \alpha_3 \beta_2^2 \right] C_{i-1,k-2} + 2 \alpha_3 \beta_2 \beta_3 C_{i-1,k-3} + \alpha_3 \beta_3^2 C_{i-1,k-4} .
\end{aligned} \tag{11}$$

Obviously, for $\alpha_3 = \beta_3 = 0$ this reduces to (8).

It is worth noting that not only the new coefficients γ , introduced in (9), become more complicated, but also that their number no longer agrees with those of α and β .

I have just been informed by Mme M. Boutillon, a colleague at the BIPM, that the following general rule holds: If the recurrence formulae for both A and B have m terms (in α and β), the recurrence for C includes $(m-1)^2+1$ terms (γ).

This nice result explains why we find five terms in the product of triple recursions ($m=3$). In addition, it shows that only in the case of a double recursion ($m=2$) - the case $m = 1$ is of no interest - the elements of the product matrix have the same number of terms in the recurrence.
